

| Phases   |   |   |
|----------|---|---|
| Analysis | <ul style="list-style-type: none"> <li>• Historical goals e.g. allow people to access historical information from anywhere in the world.</li> <li>• Privileges can be given to administrator and program manager only so that anyone else can not misuse those privileges.</li> </ul> |   |
| Design   | Input Validation  | During designing of online form do proper validation of name, birth date, email, contact number, address, username etc. Otherwise this section can be used by attacker for input validation.                  |
|          | Authentication  | Only authorised user should get access to website otherwise hacker can perform any of the following activity Network eavesdropping, brute force attacks, dictionary attacks, cookies reply, credential theft. |
|          | Authorization   | Identify all roles (admin, program manager, account manager, registered user, new user) properly then give privileges according to the roles.   |
|          | S e n s i t i v e management  | Access to sensitive data like user details, shopping details and account details should be given to registered users only, otherwise there is possibility of network eavesdropping, data tampering.           |

**Aim:** To implement a security framework (secure software lifecycle) for Museum management System.

|  |                          |   |
|--|--------------------------|---|
|  | S e s s i o n management | Once the user login till that user is going to logout his session should get maintain properly. |
|--|--------------------------|---|

|                                  |                                |   |
|----------------------------------|--------------------------------|---|
|                                  | Cryptography                   | we need encrypted password so keys for encryption and decryption should be strong so that password will not get reveal.   |
|                                  | P a r a m e t e r manipulation | Parameters passed by clients like UserId, username, password, contact number, email should be manipulated properly by removing suspicious special characters.   |
|                                  | Exception mgmt                 | Error should get handled properly, it should not reveal any program information   |
| <b>Implem<br/>e-<br/>ntation</b> | Input Validation               | Validate all text boxes, remove special characters like < , > , from otherwise SQLIA,XSS and BOF is possible  |
|                                  | Authentication                 | Instead of using only registration and password use biometric registration otherwise hacker can get access to your database   |
|                                  | Authorization                  | Identify all roles (admin, program manager, account manager, registered user, new user) properly then give privileges according to the roles. Make proper use of grant command.   |
|                                  | S e n s i t i v e management   | Access to sensitive data user details, shopping details and account details should be given to administrator only , otherwise there is possibility of network eavesdropping, data tampering.                                      |
|                                  | S e s s i o n management       | Once the user login till that user is going to logout his session should get maintain properly using Http Session Objects or any other session tracking technique. Otherwise attacker hijack any session.                         |
|                                  | Cryptography                   | For sorting password, barcode and fingerprints in database we need encrypted data so keys for encryption and decryption should be strong so that data will not get reveal. Use proper DES or AES systems or Quantum Key Protocol. |

|                         |  |  |
|-------------------------|--|--|
|                         | P a r a m e t e r<br>manipulation  | Parameters passed by clients like registration number, finger prints, password, email should be manipulated properly by removing suspicious special characters and spaces should get replace with hexadecimal symbols. |
|                         | E x c e p t i o n<br>management  | Error should get handled properly, it should not reveal any program information  |
| <b>Testing</b>          | Improper test data: Most published literatures introduce techniques for generating test cases from UML models, such as sequence diagrams or activity diagrams, and so on. Any diagram-based test method is based on path traversing. A run driven by one test case may not detect the modelled threats, so various runs taking different paths may be necessary to find a path which can activate the threat behaviour. Killing criteria should get defined properly. Design test data such a way that it will cover paths.                  |  |
| <b>Deploy<br/>ment</b>  | <p>Network Threats: All network guards like firewall, application firewall, honey-pot and IDS should be updated otherwise following threats are present Information gathering, Sniffing or eavesdropping , spoofing, Session hijacking, Denial of service</p> <p>Server Threats : Server on which I am going to deploy “museum mangmt System” should be secure otherwise following threats are possible Viruses , Trojan horse and worms Foot printing Password cracking Denial of service Arbitrary code execution Unauthorized access.</p> |  |
| <b>Mainten<br/>ance</b> | All tables used in “Museum management System” should be updated properly.  |  |
